Table of Contents

1. Introduction
2. Dataset Validation
3. System Modeling

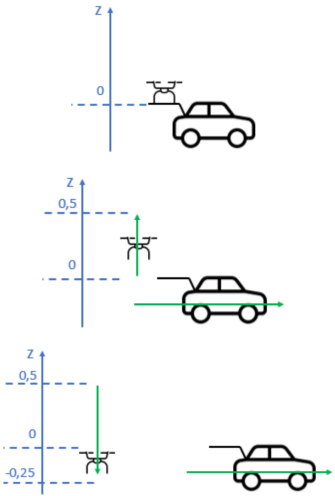

Project Objectives

Available Resources:

- Dataset of vertical acceleration.
- MATLAB/Simulink drone simulator.

Objectives:

- Validate the dataset.
- Identify the model.
- Develop a control law.

Dataset Validation

Cleaning the data

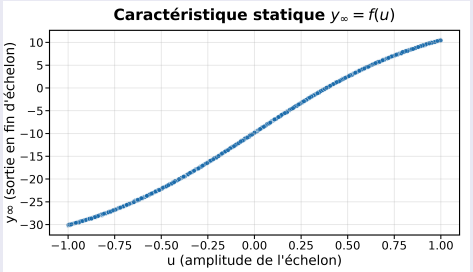

Remove lines that includes:

- Frozen sensor for 2+ seconds
- 5+ diverging values

Normalisation

- Directly in the training

Static characteristic

$y_\infty = f(u)$ after eliminating corrupted runs.

System Modeling

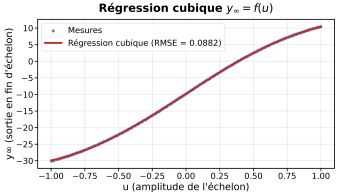

Linear Model: Hammerstein Approach

Static Characteristic $N(u)$

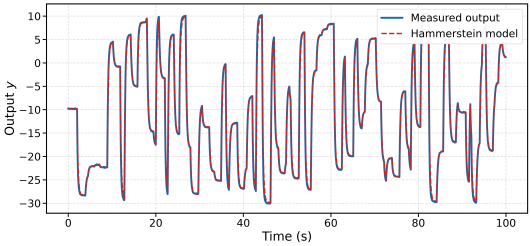

3rd-order polynomial identified on steady-state regimes:

$$v(t) = N(u) = a_3 u^3 + a_2 u^2 + a_1 u + a_0$$

Tau identification

Hammerstein Model Validation

Least-Squares Linear Model Validation (a=0.7836, b=4.9676, c=-2.1222)

System Modeling

Linear Model: Least Square Method

Model equations

$$y_k(t+1) = a\,y_k(t) + b\,u_k(t) + c$$
$$= \varphi_k^{\mathsf{T}}\theta.$$

$$\varphi_k^{\mathsf{T}} = \begin{bmatrix} y_k(t) & u_k(t) & 1 \end{bmatrix} \qquad \theta = \begin{bmatrix} a & b & c \end{bmatrix}^{\mathsf{T}}.$$

The least-squares estimate is

$$\theta^{\star} = \left(\Phi^{\mathsf{T}}\Phi\right)^{-1}\Phi^{\mathsf{T}}Y.$$
